A KEY TO RECENT SORICIDAE OF THE WESTERN UNITED STATES AND CANADA BASED PRIMARILY ON DENTARIES

LESLIE N. CARRAWAY

Department of Fisheries and Wildlife Nash 104 Oregon State University Corvallis, Oregon 97331-3308, USA

ABSTRACT Dentaries of Notiosorex crawfordii, Cryptotis parva, three species of Blarina, and 26 species of Sorex from west of the Mississippi River (U.S.) and 94°W (Canada) were examined for distinguishing characters. Additionally, subspecies of four species of Sorex that exhibited sufficient morphological differences were considered separately. Twenty quantitative characters and states for 12 qualitative characters were used to develop a key that can resolve the identifications of the 35 taxa under consideration primarily by use of the dentaries.

Key words: Soricidae; Blarina; Cryptotis; Notiosorex; Sorex; Dentary; Mandible; Identification; Western North America.

In the western United States and Canada, most soricid remains in fossil matrix, raptor pellets, and carnivore droppings are dentaries (and some rostral elements). However, few species-specific characters for dentaries have been described, and skin characteristics often are the primary basis by which some species of shrews are distinguished. Therefore, when the skin is missing or deteriorated beyond use, identification to species is difficult. Ognev (1962) and Gureev (1971) used a combination of nearly equal numbers of dentary and cranial characters to describe and distinguish taxa of fossil and Recent Palearctic soricids. In describing the subfamilies and

genera of soricids, Repenning (1967) considered a combination of characters of the mandible and rostrum. Subsequently, application of dentary characters to separate species of soricids was limited and sporadic (Butler et al., 1989; Carraway, 1990; Diersing, 1980; Foresman and Jensen, 1992; Handwerk, 1987; Harris and Carraway, 1993; Hausser and Jammot, 1974; Jammot, 1972a, b; Junge and Hoffmann, 1981; Junge et al., 1983; Mullican and Carraway, 1990; Ruprecht, 1971; Schaefer, 1975; Vesmanis et al., 1980; Wilson, 1985; Woodman and Timm, 1992). The purpose of this paper is to provide a means of identifying soricids from western North America, north of Mexico, to species based primarily on features of the dentary. Identification of soricid species should facilitate a better understanding of the diet composition of predators and the structure of fossil and Recent small-mammal communities.

MATERIALS AND METHODS

Specimens of *Notiosorex crawfordi*, *Cryptotis parva*, three species of *Blarina*, and 26 species of *Sorex* from west of the Mississippi River (United States) and 94°W (Canada) were identified by use of published cranial and skin characteristics (Carraway, 1987, 1990; Diersing, 1980; Hall, 1981; Hennings and Hoffmann, 1977; van Zyll de Jong, 1980, 1982). *Blarina brevicauda* also was distinguished by use of morphological characters, but specimens of *B. carolinensis* (2n = 37–39, 46, FN = 44–45) and *B. hylophaga* (2n = 52, FN = 60–62) were those for which diploid number and fundamental number had been determined (George et al., 1982). Subspecies of *S. bendirii*, *S. monticolus*, *S. sonomae*, and *S. trowbridgii* that exhibited sufficient morphological differences were considered separately.

Complete dentaries for each taxon were examined for distinguishing characters. Specimens of taxa examined were selected from throughout their western distributions and included all age classes (Jackson, 1928). Nevertheless, it is possible to encounter individuals that exceed the range of variation of these samples. Only one karyotyped *Blarina carolinensis* from west of the Mississippi River was available; consequently, 15 from elsewhere in the range were used to verify identifying characteristics.

For each dentary, states for 12 qualitative characters (Fig. 1) were evaluated and 20 quantitative characters (Fig. 2; Tables 1, 2) were measured by use of an ocular micrometer and ocular protractor mounted in a Bausch and Lomb binocular microscope. Terminology for tooth morphology follows that of Butler et al. (1989), Choate (1970), Dannelid (1989), and Hershkovitz (1971). Dentary tooth nomenclature follows that of Hall (1981): iI, cI, pA, mI, m2, and m3.

Some characters in the key were used previously (Butler et al., 1989; Carraway, 1987; Carraway and Verts, 1994; Dannelid, 1989; Harris and

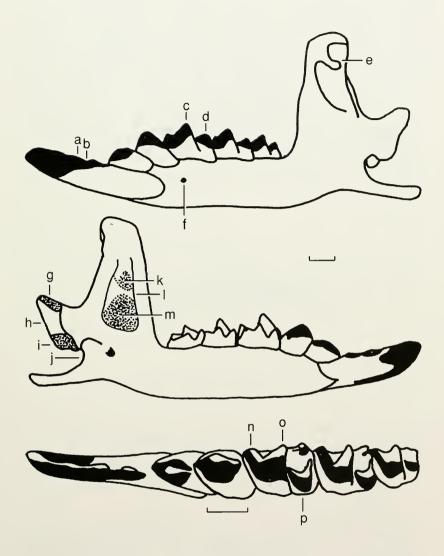

Fig. 1. Labial (top) and lingual (middle) views of dentary, and occlusal (bottom) view of mandibular tooth row of *Sorex* to illustrate qualitative characters examined. Key to characters: a = denticle; b = interdenticular space; c = paraconid; d = hypoconid; e = coronoid spicule; f = mental foramen; g = superior condylar process; h = interarticular area; i = inferior condylar process; j = lower sigmoid notch; k = superior opening of temporal fossa; l = internal temporal fossa; m = inferior opening of temporal fossa; n = paraconid; o = protoconid; and p = hypoconid. Scales in this and all other figures are 1 mm.

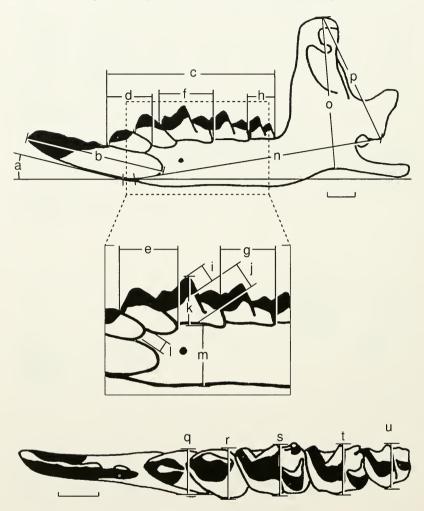

Fig. 2. Labial (top) and occlusal (bottom) views of a *Sorex* dentary to illustrate quantitative characters measured. Key to characters: a = angle e (i.e., iI set at an angle e from the horizontal ramus of the dentary); b = length of iI (used only with *Sorex hendirii*); c = length of mandibular tooth row (i.e., cI-m3); d = length of cI; e = length of p4; f = length of m1; g = length of m2; h = length of m3; h = length of pigmented portion of mI; h = length of unpigmented portion of mI; h = length of dentary below mI; h = length of dentary; h = length of coronoid process; h = length of coronoid-condyloid processes; h = length of h = length

Carraway, 1993; Handwerk, 1987; Hausser, 1984; Repenning, 1967). For dimensions in which tooth designations are separated by a dash (e.g., c1–m3), the specified teeth were measured as a unit from the most anterior point to the most posterior point. For dimensions in which tooth designations are separated by a plus (+), the length of each tooth was measured individually and the values summed. This distinction is necessary, because unlike the mandibular teeth of most mammals, soricid mandibular teeth overlap one another to a considerable extent.

The key is dichotomous. Because some species are composed of geographic races of disparate sizes, it is possible for a species to be identified in more than one couplet. Camera-lucida tracings illustrate states of the qualitative characters examined and various views of the dentaries. Figures of the dentaries are drawn to the same scale and in the same orientation; however, they are not all printed to the same scale because of publishing constraints. All scale bars represent 1 mm.

Species comparisons of taxa of similar size or close geographic proximity either now or possibly during the Pleistocene follow the key. In a few instances in which no quantitative or qualitative dentary characters could be discerned, rostral characters were used. Species are listed in alphabetical order.

KEY TO THE DENTARIES

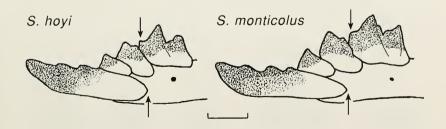

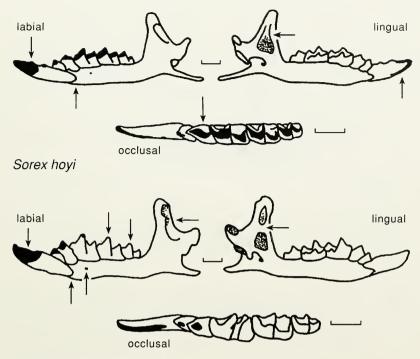

Fig. 3. Labial view of the anterior half of dentaries to illustrate *Sorex hoyi* (KU 37149) with the alveolus of *il* (lower arrow) extending beneath *ml* (upper arrow), and *S. monticolus* (OSUFW 4747) with the alveolus of *il* not extending beneath *ml*.

Internal temporal fossa composed of an inferior round opening separated from a superior depression by a bar (Fig. 4); iI with one or two denticulations (Fig. 4); length of dentary > 6.1 mm; length of cI-m3 > 4.2 mm; height of coronoid process ≥ 3.4 mm 3

Notiosorex crawfordi

Fig. 4. Dentaries of *Sorex hoyi* (ROM 10736) and *Notiosorex crawfordi* (MSB 47947). In both taxa, note number of denticulations, relationship of posterior edge of *i1* to *m1*, and structure of internal temporal fossa. *Sorex hoyi* has pigment on posterior portion of ventromedial edge of *i1* and one posterolingually directed ridge on *p4*. *Notiosorex crawfordi* lacks pigment on *m2* and *m3*.

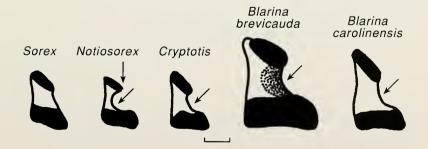

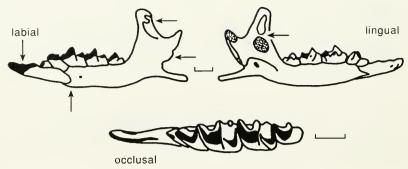

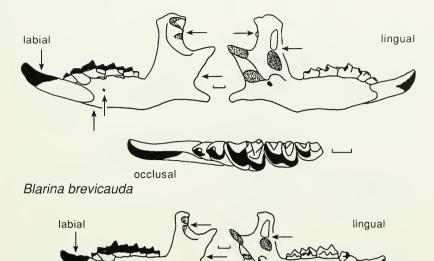

Fig. 5. Posterior views (labial to left) of condylar processes of soricids. Note the differences in the relative widths of the superior and inferior condylar processes, the amount of emargination in the lingual side of interarticular areas, and the presence or absence of a basin in the lingual side of interarticular areas.

Cryptotis parva

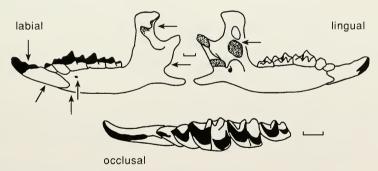

Fig. 6. Dentary of *Cryptotis parva* (OSUFW 4475). Note the numbers of denticulations, the relationship of the posterior edge of il to ml, size of the coronoid spicule, and structure of the internal temporal fossae.

5(4).	Height of coronoid process usually ≥ 6.0 mm; length of $c1$ – $m3$ usually ≥ 6.5 mm; length of coronoid-condyloid processes usually ≥ 5.2 mm; mental foramen positioned beneath hypoconid of $m1$; basin in lingual side of interarticular area (Fig. 5)
	Height of coronoid process \leq 6.0 mm; length of $c1$ – $m3$ \leq 6.5 mm; length of coronoid-condyloid processes usually $<$ 5.0 mm; mental foramen positioned beneath midpoint between protoconid and hypoconid of $m1$; no basin in lingual side of interarticular area (Fig. 5)
6(5).	First lower incisor set at an angle ≤ 17° from the horizontal ramus of the dentary (Fig. 7)
	First lower incisor set at an angle ≥ 18° from the horizontal ramus of the dentary (Fig. 7)
7(1).	Length of dentary usually ≥ 7.7 mm; height of coronoid process \geq 4.0 mm; length of $c1$ – $m3 \geq 4.9$ mm
	Length of dentary usually ≤ 7.7 mm; height of coronoid process ≤ 4.0 mm; length of $c1-m3 < 5.0$ mm

occlusal

Blarina carolinensis

Blarina hylophaga

Fig. 7. Dentaries of *Blarina brevicauda* (OSUFW 7777), *B. carolinensis* (OSUFW 3325), and *B. hylophaga* (FHSU 10166). In all taxa, note the numbers of denticulations, the relationship of the posterior edge of *il* to *m1*, the sizes of the coronoid spicules, the structures of the internal temporal fossae, and the obscured inferior condylar process in labial view. The mental foramen is located beneath the hypoconid of *m1* in *B. brevicauda*, whereas it lies beneath the midpoint between the protoconid and hypoconid of *m1* in *B. carolinensis* and *B. hylophaga*. Note angle of *i1* relative to horizontal ramus of dentary in *B. carolinensis* and *B. hylophaga*.

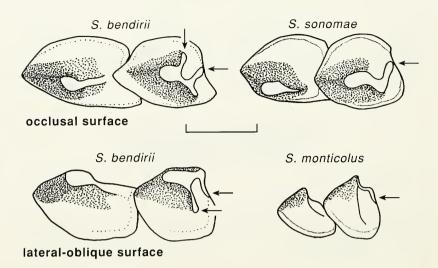

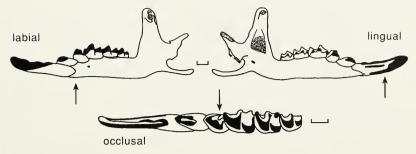

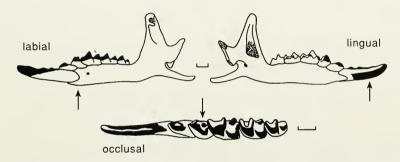

Fig. 8. Views of *c1* and *p4* (anterior to left) to show posterolingually directed ridges on the occlusal surface of *p4* of *Sorex bendirii* (OSUFW 4873), *S. sonomae* (KU 145866), *S. bendirii* (OSUFW 4873), and *S. monticolus* (OSUFW 4815). Note the presence of two ridges in *S. bendirii* and only one ridge in the other *Sorex*.

8(7).	Two posterolingually directed ridges on occlusal surface of $p4$ (Fig. 8); length of $c1$ > length of $p4$
	One posterolingually directed ridge on occlusal surface of $p4$ (Fig. 8); length of $c1 \le$ length of $p4$
9(8).	Width of cI + width of $p4$ usually ≥ 1.8 mm; length of iI usually ≥ 5.4 mm ($\bar{x} = 5.85$, SE = 0.07, $n = 29$, range 5.2–6.5, CV = 0.06)
	Width of cl + width of $p4$ usually ≤ 1.8 mm; length of il usually ≤ 5.4 mm ($\bar{x} = 5.16$, SE = 0.05, $u = 29$, range 4.7–5.7, CV = 0.05)
10(8).	No strip of pigment on inside of ventromedial edge of <i>ils</i> where they meet (Fig. 10)
	Strip of pigment on inside of ventromedial edge of <i>ils</i> where they meet (Fig. 10)

Sorex bendirii palmerii

Sorex bendirii (other subspecies)

Fig. 9. Dentaries of *Sorex bendirii palmeri* (OSUFW 1483) and other subspecies of *S. bendirii* (represented by USNM 233594). Note the relationship of the posterior edge of il to ml, the presence of pigment on the posterior portion of the ventromedial edge of il, and the two posterolingually directed ridges on p4.

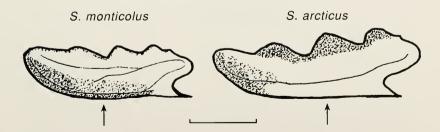

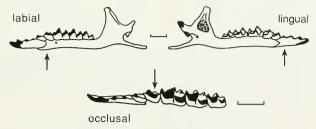

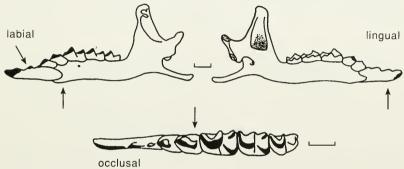

Fig. 10. Lingual views (anterior to the left) of *i1* of *Sorex monticolus* (OSUFW 4747) and *S. arcticus* (KU 45299) to show differences in the posterior extent of the pigment on the ventromedial edge of *i1*.

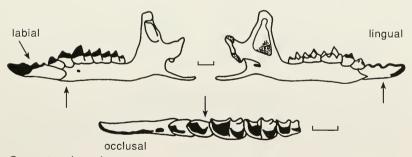

11(10).	Length of $c1-m3 \le 2.7$ mm; length of dentary ≤ 6.0 mm; depth of dentary below $m1 \le 0.6$ mm; height of coronoid process ≤ 2.7 mm
	Length of $c1-m3 \ge 4.5$ mm; length of dentary > 6.8 mm; depth of dentary below $m1 \ge 1.0$ mm; height of coronoid process ≥ 3.7 mm
12(11).	Pigment on il in two or three sections (Fig. 11); height of coronoid process ≥ 4.4 mm; length of coronoid-condyloid processes ≥ 3.8 mm; length of dentary ≥ 7.9 mm; depth of dentary below ml + height of coronoid process ≥ 5.6 mm
	Pigment on il in one section (Fig. 11) may be obscured in old adults; height of coronoid process ≤ 4.2 mm; length of coronoid-condyloid processes ≤ 3.6 mm; length of dentary ≤ 7.9 mm; depth of dentary below ml + height of coronoid process ≤ 5.2 mm Sorex tundrensis, Tundra shrew (Fig. 11)
13(10).	Height of coronoid process ≤ 4.2 mm; length of coronoid-condy-loid processes usually ≤ 3.6 mm; depth of dentary below ml + height of coronoid process usually ≤ 5.2 mm
	Height of coronoid process ≥ 4.3 mm; length of coronoid-condy-loid processes ≥ 3.6 mm; depth of dentary below ml + height of coronoid process usually ≥ 5.3 mm
14(13).	Mental foramen usually positioned beneath posterior half of <i>m1</i> (Fig. 12)
	Mental foramen usually positioned beneath anterior half of <i>m1</i> (Fig. 12)
15(14)	First lower incisor set at an angle $8{\text -}10^\circ$ from the horizontal ramus of the dentary (Fig. 12); distance between il and $p4 \le 0.3$ mm Sorex trowbridgii montereyensis, Trowbridge's shrew (Fig. 12)
	First lower incisor set at an angle $10-15^{\circ}$ from the horizontal ramus of the dentary (Fig. 12); distance between iI and $p4 \ge 0.4$ mm all other <i>Sorex trowbridgii</i> , Trowbridge's shrew (Fig. 12)

Sorex minutissimus

Sorex arcticus

Sorex tundrensis

Fig. 11. Dentaries of *Sorex minutissimus* (UAM 19268), *S. arcticus* (ROM 11622), and *S. tundrensis* (UAM 13561) showing relationship of posterior edge of *i1* to *m1*, the lack of pigment on the posterior portion of the ventromedial edge of *i1*, and one posterolingually directed ridge on *p4*. Note number of pigment sections on *i1* of *S. arcticus* and *S. tundrensis*.

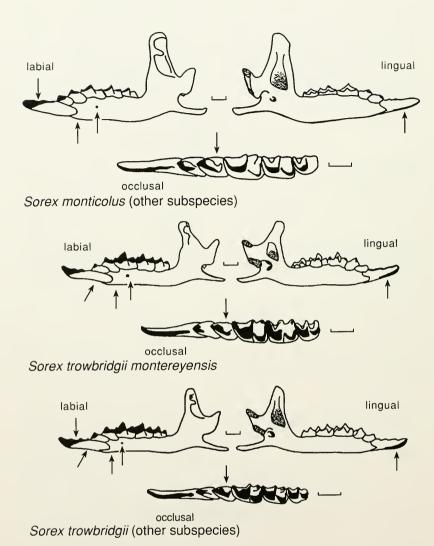

Fig. 12. Dentaries of *Sorex monticolus* (OSUFW 6055), *S. trowbridgii montereyensis* (KU 68098), and other subspecies of *S. trowbridgii* (represented by OSUFW 6111). Note the relationship of the posterior edge of il to ml, the position of the mental foramen relative of ml, one posterolingually directed ridge on p4, and the presence of pigment on the posterior portion of the ventromedial edge of il. In *S. monticolus* and other subspecies of *S. trowbridgii* note the very deep interdenticular space. In all *S. trowbridgii* note the angle of il relative to the horizontal ramus of the dentary.

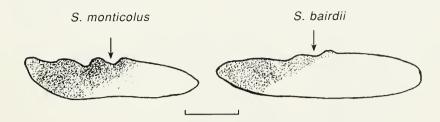

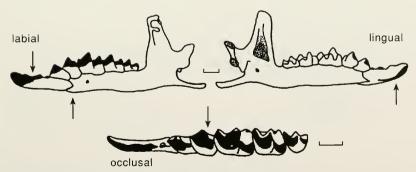

Fig. 13. Labial views (anterior to the left) of the *ils* of *Sorex monticolus* (OSUFW 4747) to show the deep interdenticulations and of *S. bairdii* (OSUFW 7261) to show the shallow interdenticulations.

Sorex monticolus neomexicanus

Fig. 14. Dentary of *Sorex monticolus neomexicanus* (MSB 37345) showing very deep interdenticular space, relationship of posterior edge of il to ml, one posteriolingually directed ridge on p4, and presence of pigment on the posterior portion of ventromedial edge of il.

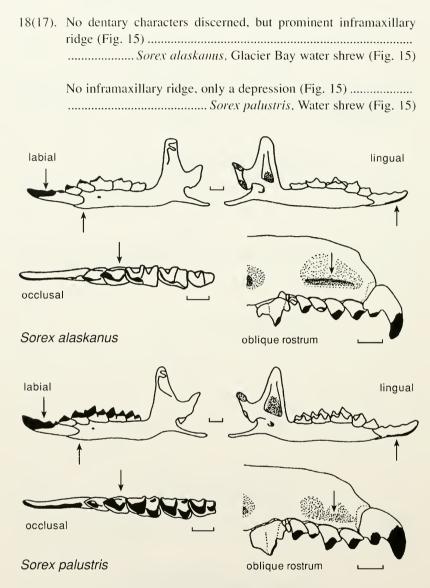

Fig. 15. Dentaries and rostrums (in oblique view at lower right) of *Sorex alaskanus* (USNM 97712) and *S. palustris* (OSUFW 4857). Note in the dentaries of both taxa the very deep interdenticular space, the relationship of the posterior edge of il to ml, and one posterolingually directed ridge on p4, and presence of pigment on the posterior portion of the ventromedial edge of il. The rostrum of *S. alaskanus* has a prominent inframaxillary ridge, whereas that of *S. palustris* has a depression.

Length of ml usually ≤ 1.7 mm; width of cl + width of p4 usually ≤ 1.8 mm Sorex sonomae tenelliodus, Fog shrew (Fig. 17)

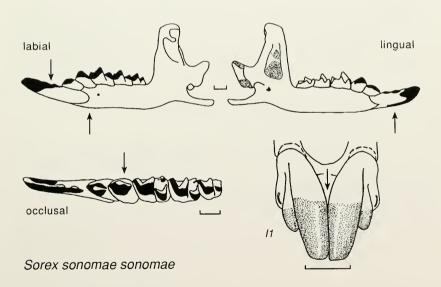

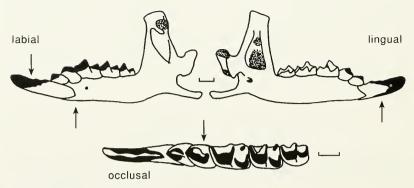

Fig. 16. Dentary and anterior view of il (at lower right) of *Sorex sonomae sonomae* (OSUFW 8876). In the dentary note the shallow interdenticular space, the relationship of the posterior edge of il to ml, one posterolingually directed ridge on p4, and presence of pigment on the posterior portion of the ventromedial edge of il. The medial edge of each il lacks a projection.

Sorex sonomae tenelliodus

- Fig. 17. Dentary of *Sorex sonomae tenelliodus* (OSUFW 7206) showing the shallow interdenticular space, the relationship of the posterior edge of il to ml, one posterolingually directed ridge on p4, and presence of pigment on the posterior portion of the ventromedial edge of il.
- 21(19). No dentary characters discerned, but small median tine present on IIs (Fig. 18)Sorex bairdii, Baird's shrew (Fig. 18) Ridge present at posteromedial edge of *IIs* (Fig. 18) Length of dentary usually ≤ 6.5 mm; length of c1–m3 usually < 4.122(7). mm; height of coronoid process $\leq 3.2 \text{ mm} \dots 23$ Length of dentary usually ≥ 6.5 mm; length of c1– $m3 \geq 4.1$ mm; Pigment on il in one or two sections (Fig. 19), rarely three as a 23(22). result of wear; dentary below m1 shallower than height of m1 ... Sorex nanus, Dwarf shrew (Fig. 19) Pigment on i1 usually in three sections (Fig. 19); dentary below m1 as deep as or deeper than height of m124 24(23). First lower incisor set at an angle $\leq 8^{\circ}$ from the horizontal ramus of the dentary (Fig. 19); width of $m1 \le 0.8$ mm; width of $m2 \le 0.8$ First lower incisor set at an angle ≥ 8° from the horizontal ramus of the dentary (Fig. 19); width of $m1 \ge 1.1$ mm; width of $m2 \ge 0.9$

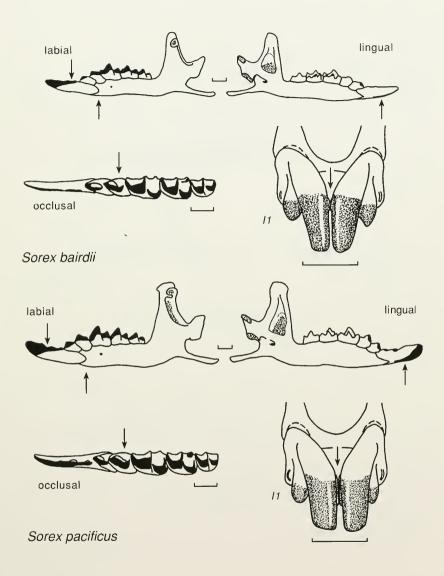

Fig. 18. Dentaries and anterior views of *i1s* (at lower right) of *Sorex hairdii* (OSUFW 6111) and *S. pacificus* (OSUFW 8306). In the dentaries of both taxa note the shallow interdenticular space, the relationship of the posterior edge of *i1* to *m1*, one posterolingually directed ridge on *p4*, and presence of pigment on the posterior portion of the ventromedial edge of *i1*. Each *i1* of *S. bairdii* bears a small median tine, whereas each *i1* of *S. pacificus* bears a ridge along the posteromedial edge.

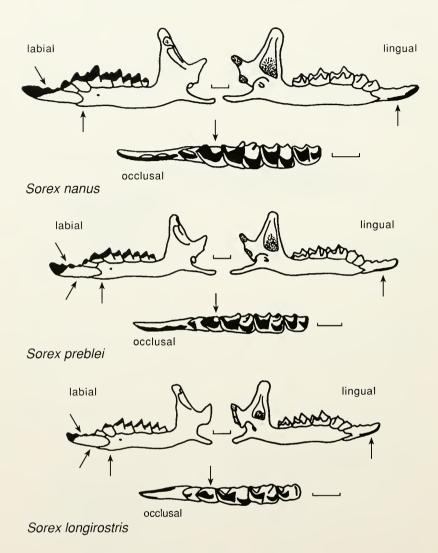

Fig. 19. Dentaries of *Sorex nanus* (MSB 59339), *S. preblei* (OSUFW 4435), and *S. longirostris* (MSUMZ 24168). Note the number of pigment sections on iI, the relationship of the posterior edge of iI to mI, and one posterolingually directed ridge on pI, and presence of pigment on the posterior portion of the ventromedial edge of iI in all taxa. In *S. preblei* and *S. longirostris* note the angle of iI relative to the horizontal ramus of the dentary.

25(22).	Height of coronoid process ≤ 3.2 mm; c1 with two cusps
	Height of coronoid process usually ≥ 3.2 mm; cI usually with one cusp, but if with two cusps, height of coronoid process ≥ 3.4 mm 26
26(25).	Length of coronoid-condyloid processes usually ≤ 3.1 mm; length of ml + length of $m2$ usually ≤ 2.4 mm
	Length of coronoid-condyloid processes usually ≥ 3.1 mm; length of ml + length of $m2$ usually ≥ 2.4 mm
27(26).	Pigment on <i>i1</i> distributed in one section (Fig. 20)
	Pigment on <i>i1</i> distributed in two or three sections (Figs. 20, 21, 22)
28(27).	Present geographic range limited to Sierra Nevada mountains, Mono Co., California (Williams, 1984); pelage bicolored
	Present geographic range not including California; pelage bicolored or tricolored
29(28).	Present geographic range limited to Pribliof Islands, Alaska; pelage tricolored
	Present geographic range other than Pribliof Islands, Alaska; pelage bicolored
30(29).	Pigment on il distributed in two sections (Fig. 21); il set at an angle $\geq 8^{\circ}$ from the horizontal ramus of the dentary (Fig. 21) Sorex hydrodromus, Pribilof Island shrew (Fig. 21)
	Pigment on il distributed in three sections (Fig. 21); il set at an angle $\leq 8^{\circ}$ from the horizontal ramus of the dentary (Fig. 21)
31(29).	No dentary characters discerned, but maxillary breadth < 4.15 mm (Jackson, 1928; zygomatic processes commonly broken in specimens of old adults) <i>Sorex cinereus</i> , Masked shrew (Fig. 21)
	Maxillary breadth ≥ 4.15 mm (Jackson, 1928; zygomatic processes commonly broken in specimens of old adults)

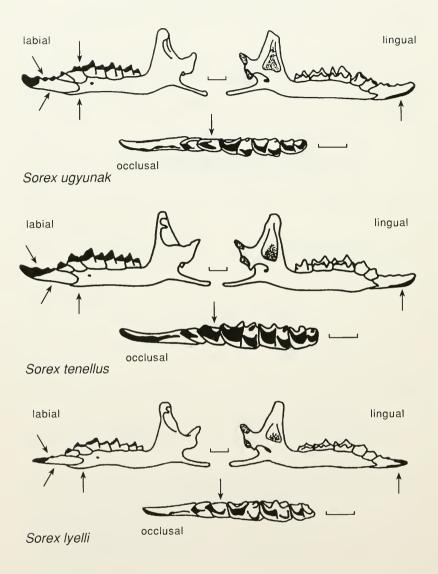

Fig. 20. Dentaries of *Sorex ugyunak* (KU 43166), *S. tenellus* (LACM 85713), and *S. lyelli* (LACM 85453). In all taxa note the number of pigment sections on il, the angle of il relative to the horizontal ramus of the dentary, the relationship of the posterior edge of il to ml, one posterolingually directed ridge on p4, and presence of pigment on the posterior portion of the ventromedial edge of il. In *S. ugyunak*, cl bears two cusps.

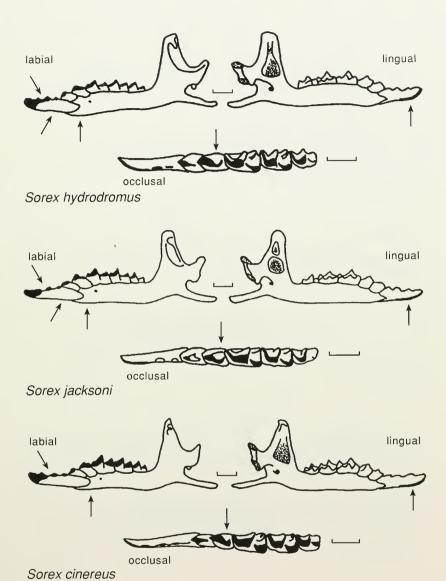

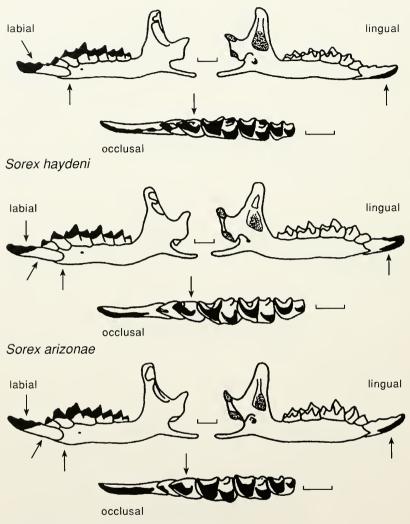

Fig. 21. Dentaries of *Sorex hydrodromus* (UAM 13562), *S. jacksoni* (UAM 7794), and *S. cinereus* (OSUFW 7796). In all taxa note the number of pigment sections on *i1*, the relationship of the posterior edge of *i1* to *m1*, one posterolingually directed ridge on *p4*, and presence of pigment on the posterior portion of the ventromedial edge of *i1*. In *S. hydrodromus* and *S. jacksoni* note the angle of *i1* relative to the horizontal ramus of the dentary.

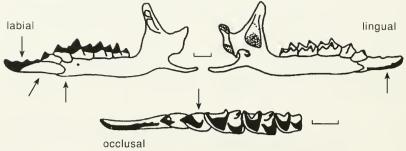

Sorex merriami

Fig. 22. Dentaries of *Sorex haydeni* (OSUFW 3278), *S. arizonae* (UIMNH 49494), and *S. merriami* (OSUFW 3348). In all taxa note the relationship of the posterior edge of *i1* to *m1*, one posterolingually directed ridge on *p4*, and presence of pigment on the posterior portion of the ventromedial edge of *i1*. In *S. haydeni* note the number of pigment sections on *i1*. In *S. arizonae* and *S. merriami* note the very shallow interdenticular space and the angle of *i1* relative to the horizontal ramus of the dentary.

32(26).	First lower incisor set at an angle $\geq 13^{\circ}$ from the horizontal ramus of the dentary; interdenticular space very shallow (Fig. 13) 33
	First lower incisor set at an angle $\leq 13^{\circ}$ from the horizontal ramus of the dentary; interdenticular space very deep (Fig. 13), may be obscured in old individuals
33(32).	Height of coronoid process ≤ 3.8 mm; ratio of height of coronoid process:length of dentary ≤ 0.54 ; ratio of distance between <i>i1</i> and $p4$: length of dentary ≥ 0.04
	Height of coronoid process usually ≥ 3.9 mm; ratio of height of coronoid process:length of dentary ≥ 0.55 ; ratio of distance between $i\dot{l}$ and $p4$: length of dentary ≤ 0.04
34(32).	No dentary characters discerned, but median tines on <i>IIs</i> set at or above the pigment on the body of the <i>IIs</i> (Fig. 23)
	Median tines on <i>IIs</i> set within the pigment on the body of the <i>II</i> . (Fig. 23)
S	. trowbridgii S. vagrans S. monticolus

Fig. 23. Anterior views of *ils* of *Sorex trowbridgii* (PSM 5892), *S. vagrans* (SDMNH 16971), and *S. monticolus* (KU 146134). Notice that in *S. trowbridgii* and *S. vagrans* the tines are above the level of the pigment; however, in *S. trowbridgii* the medial edges of the *ils* are curved and flaring, whereas they are straight and minimally divergent in *S. vagrans*. In *S. monticolus* the median tines are set within the pigment.

Sorex vagrans

- Fig. 24. Dentary of *Sorex vagrans* (OSUFW 6821) showing the very deep interdenticular space, the angle of il relative to the horizontal ramus of the dentary, the relationship of the posterior edge of il to ml, one posterolingually directed ridge on p4, and presence of pigment on the posterior portion of the ventromedial edge of il.

Paracrista partially to completely pigmented on *P4* (Fig. 25) *Sorex monticolus*, Dusky or Montane shrew (Fig. 12)

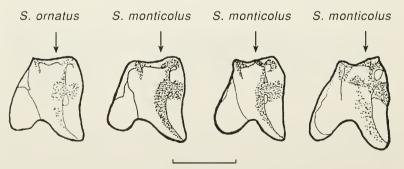

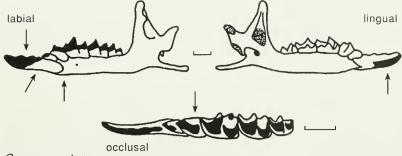

Fig. 25. Occlusal views (lingual to the left) of upper *P4* of *Sorex ornatus* (KU 50218) and three specimens of *S. monticolus* (left to right: OSUFW 4798, 4799, and 4815) to show the absence of pigment on the paracrista in *S. ornatus* and the variable amounts of pigment on the paracrista in *S. monticolus*.

Sorex ornatus

Fig. 26. Dentary of *Sorex ornatus* (UCD 4688) showing the very deep interdenticular space, the angle of il relative to the horizontal ramus of the dentary, the relationship of the posterior edge of il to ml, one posterolingually directed ridge on p4, and presence of pigment on the posterior portion of the ventromedial edge of il.

COMPARISONS OF SOME SPECIES OF SORICIDAE

Selected species not in direct line in the key are compared in the following annotations of aspects of their morphology.

Notiosorex crawfordi (**Desert shrew**)

Notisorex crawfordi can be distinguished from all other soricids in the western United States and Canada by possession of the following combination of characters: alveolus of il extending posteriorly beneath at least part of ml (Figs. 3, 4); no pigment on m2 and m3 (Fig. 4); and deeply emarginate interarticular area (Fig. 5). However, these three characters may not be sufficient to identify to species old individuals with excessively worn teeth or a damaged dentary. The desert shrew can be separated from $Sorex\ hoyi$, $S.\ merriami$, $S.\ ornatus$, and $S.\ preblei$ by height of the unpigmented portion of $ml \ge 0.9$ mm; from $S.\ hoyi$, $S.\ nanus$, and $S.\ preblei$ by height of the coronoid process ≥ 3.5 mm and length of $cl-m3 \ge 4.5$ mm; and from $S.\ hoyi$ and $S.\ ornatus$ by il set at an angle $\ge 15^\circ$ from the horizontal ramus of the dentary. Additionally, $N.\ crawfordi$ differs from $S.\ hoyi$ by the width of $ml \ge 0.8$ mm, width of $ml \ge 0.8$ mm, and length of the dentary ≥ 6.1 mm, and from $S.\ preblei$ by length of the coronoid-condyloid processes ≥ 3.0 mm.

Sorex alaskanus (Glacier Bay water shrew)

The Glacier Bay water shrew differs from *Sorex arcticus*, *S. monticolus*, and *S. ugyunak* by length of $cl-m3 \ge 5.4$ mm. Also, it differs from *S. arcticus* by presence of a strip of pigment on the inside ventromedial edge

of the *i1s* (Figs. 10, 15) and by the length of the coronoid-condyloid processes ≤ 3.7 mm, and from *S. ugyunak* > 3.5 mm. *Sorex alaskanus* is distinguished from *S. monticolus* and *S. ugyunak* by length of the dentary ≥ 8.6 mm. Additionally, it can be distinguished from *S. ugyunak* by height of the coronoid process ≥ 4.2 mm, depth of the mandible at $ml \geq 1.3$ mm, by pigment on *i1* in one section, and *c1* with one cusp.

Sorex arcticus (Arctic shrew)

Sorex arcticus differs from S. alaskanus, S. cinereus, S. jacksoni, S. hydrodromus, S. monticolus, and S. ugyunak by length of the coronoid-condyloid processes ≥ 3.8 mm and lack of a strip of pigment on the inside ventromedial edge of the ils (Figs. 10, 11). Additionally, it can be distinguished from S. alaskanus by length of $cl-m3 \leq 5.3$ mm and from S. jacksoni, S. hydrodromus, and S. ugyunak ≥ 4.8 mm; from S. cinereus, S. jacksoni, S. hydrodromus, S. monticolus, and S. ugyunak by height of the coronoid process ≥ 4.4 mm; from S. cinereus, S. jacksoni, S. hydrodromus, and S. ugyunak by length of the dentary ≥ 7.9 mm; from S. jacksoni, S. hydrodromus, and S. ugyunak by width of $p4 \geq 0.7$ mm; from S. cinereus and S. ugyunak by width of $cl \geq 0.6$ mm; and from cl s. jacksoni and cl s. ugyunak by depth of the dentary below cl s 1.1 mm. Also, from cl s jacksoni by width of cl s 0.7 mm and from cl s ugyunak by cl s with one cusp.

Sorex arizonae (Arizona shrew)

This species can be distinguished from *Sorex hoyi* and *S. nanus* by height of the coronoid process ≥ 3.5 mm, and from *S. merriami* ≤ 3.8 mm, and from *S. hoyi* and *S. nanus* by length of c1– $m3 \geq 4.7$ mm and length of the dentary ≥ 7.1 mm. Additionally, *S. arizonae* differs from *S. hoyi* by length of $m3 \geq 0.8$ mm and the alveolus of i1 not extending posteriorly beneath part of m1 (Figs. 3, 22), and from *S. nanus* by depth of the dentary below $m1 \geq 1.0$ mm, length of the coronoid-condyloid processes ≥ 3.1 mm, length of $c1 \geq 0.9$ mm, length of $c1 \geq 0.9$ mm, length of $c1 \geq 0.7$ mm.

Sorex bairdii (Baird's shrew)

Sorex bairdii can be distinguished from S. monticolus by height of the coronoid process usually ≥ 4.3 mm and length of c1–m3 usually ≥ 5.2 mm.

Sorex bendirii (Pacific water shrew)

The condition of two posterolingually directed ridges (Fig. 8) on the occlusal surface of *p4* of the Pacific water shrew is unique among shrews in the western United States and Canada. Also, *Sorex bendirii* can be distin-

guished from all other *Sorex* by length of *c1* greater than length of *p4*. Differences in pattern of pigmentation on the *i1s* of specimens of *S. b. bendirii* and *S. b. palmeri* in Figure 9 are the result of individual variation and are not of taxonomic value.

Sorex cinereus (Masked shrew)

Sorex cinereus differs from S. arcticus, S. monticolus, S. m. neomexicanus, S. palustris, S. tundrensis, and S. vagrans by length of the coronoid-condyloid processes usually ≤ 3.2 mm; from S. hydrodronus and S. palustris by il set at an angle $\leq 8^{\circ}$ from the horizontal ramus of the dentary; and from S. arcticus and S. tundrensis by presence of a strip of pigment on the inside ventromedial edge of the ils (Figs. 10, 21). No single qualitative or quantitative character, or combination of characters recorded for this study, distinguish S. cinereus from S. jacksoni. However, van Zyll de Jong (1982; in litt., 30 January 1995) could distinguish cinereus and jacksoni by the following discriminant-function equation: discriminant score = 2.751 (length of mandible) + 3.633 (height of the coronoid process) + 6.189 (length of coronoid-condyloid processes) + 11.68 (greatest condylar depth) + 14.53 (width of lower condylar facet) – 5.923 (width of upper condylar facet) -3.874 (length of c1-m3) -17.54496. Those specimens with a score ≤ -0.293 are S. cinereus. Additionally, the masked shrew can be separated from S. arcticus and S. palustris by length of the dentary ≤ 7.6 mm and height of the coronoid process ≤ 3.9 mm and from S. ugyunak usually ≥ 3.2 mm; from S. arcticus by width of $c1 \leq 0.5$ mm; from S. palustris by length of $c1-m3 \le 4.9$ mm; from S. monticolus by length of m1 ≤ 1.4 mm; from S. m. neomexicanus by length of $ml \leq 1.4$ mm, length of $m2 \le 1.2$ mm, and height of the unpigmented portion of $m1 \le 0.6$ mm; from S. palustris by length of $m3 \le 0.9$ mm; and from S. ugyunak by c1 usually with one cusp.

Sorex haydeni (Hayden's shrew)

Hayden's shrew differs from *Sorex hoyi* by the alveolus of il not extending posteriorly beneath at least part of ml (Figs. 3, 22) and length of the dentary ≥ 6.2 mm; from *S. monticolus* by length of ml usually ≤ 1.3 mm and length of $cl-m3 \leq 4.4$ mm; and from *S. preblei* by height of the coronoid process ≥ 3.2 mm and length of cl-m3 usually ≥ 4.1 mm.

Sorex hoyi (Pygmy shrew)

This species is unique within the genus *Sorex* because the alveolus of il extends posteriorly beneath at least part of ml (Figs. 3, 4). *Sorex hoyi* can be distinguished from *Notiosorex crawfordi*, *S. arizonae*, and *S. merriami* by height of the coronoid process ≤ 3.4 mm and from *S. nanus* ≥ 3.1 mm;

from N. crawfordi and S. preblei by il set at an angle $\leq 13^{\circ}$ and $\geq 10^{\circ}$ from the horizontal ramus of the dentary, respectively; from N. crawfordi and S. arizonae by width of $ml \leq 0.8$ mm and width of $m2 \leq 0.8$ mm; and from S. haydeni and S. merriami by length of the dentary ≤ 6.1 mm. Additionally, it differs from N. crawfordi by height of the unpigmented portion of $ml \leq 0.7$ mm; from N. crawfordi, S. arizonae, and S. merriami by length of $cl-m3 \leq 4.2$ mm; from S. arizonae and S. merriami by length of $ml \geq 0.9$ mm and $ml \leq 0.8$ mm, respectively; and from $ml \leq 0.8$ mm, respectively; and from $ml \leq 0.8$ mm.

Sorex hydrodromus (Pribilof Island shrew)

The Pribilof Island shrew differs from *Sorex arcticus*, *S. monticolus*, and *S. tundrensis* by length of the coronoid-condyloid processes usually ≤ 3.1 mm and length of c1– $m3 \leq 4.5$ mm, and from *S. cinereus*, *S. jacksoni*, and *S. ugyunak* by i1 set at an angle $\geq 8^{\circ}$ from the horizontal ramus of the dentary. Additionally, *S. hydrodromus* can be distinguished from *S. arcticus* and *S. tundrensis* by presence of a strip of pigment on the inside ventromedial edge of the i1s (Figs. 10, 21) and height of the coronoid process ≤ 3.6 mm and from *S. ugyunak* ≥ 3.3 mm; from *S. arcticus* by width of $p4 \leq 0.6$ mm and length of the dentary ≤ 7.7 mm; from *S. monticolus* by length of $m1 \leq 1.3$ mm; and from *S. ugyunak* by presence of pigment on i1 in two sections and c1 usually with one cusp.

Sorex jacksoni (St. Lawrence Island shrew)

Sorex jacksoni can be distinguished from S. arcticus, S. monticolus, and S. tundrensis by length of $c1-m3 \le 4.4$ mm; from S. arcticus, S. monticolus, and S. tundrensis by length of the coronoid-condyloid processes ≤ 3.0 mm; from S. hydrodronus and S. monticolus by i1 set at an angle $\leq 7^{\circ}$ from the horizontal ramus of the dentary; and from S. ugyunak by c1 usually with one cusp. No single qualitative or quantitative character, or combination of characters recorded for this study, separates S. jacksoni from S. cinereus. However, van Zyll de Jong (1982; in litt., 30 January 1995) could distinguish jacksoni and cinereus by the following discriminant-function equation: discriminant score = 2.751 (length of mandible) + 3.633 (height of the coronoid process) + 6.189 (length of coronoid-condyloid processes) + 11.68 (greatest condylar depth) + 14.53 (width of lower condylar facet) – 5.923 (width of upper condylar facet) -3.874 (length of c1-m3) -17.54496. Those specimens with a score ≥ 0.460 are S. jacksoni. Further, it differs from S. arcticus and S. tundrensis by height of the coronoid process ≤ 3.5 mm and from S. ugyunak \geq 3.2 mm; from S. arcticus and S. monticolus by width of $p4 \le 0.5$ mm and width of $m2 \le 0.6$ mm; from S. arcticus by depth of the dentary below $mI \le 1.0$ mm and length of the dentary ≤ 7.0 mm; and from S. arcticus and S. tundrensis by presence of a strip of pigment on the inside of the ventromedial edge of the ils (Figs. 10, 21).

Sorex longirostris (Southeastern shrew)

This species can be distinguished from *Sorex hoyi*, *S. merriami*, and *S. namus* by width of $ml \ge 1.1$ mm and from *S. hoyi* and *S. namus* by width of $m2 \ge 0.9$ mm. Also, it differs from *S. hoyi* by the alveolus of il not extending posteriorly beneath part of ml (Figs. 3, 19), and from *S. merriami* by length of $cl-m3 \le 4.2$ mm, height of the coronoid process ≤ 3.3 mm, and length of the coronoid-condyloid processes ≤ 2.9 mm.

Sorex lyelli (Mt. Lyell shrew)

The Mt. Lyell shrew differs from *Sorex ornatus* and *S. vagrans* by length of the coronoid-condyloid processes ≤ 3.0 mm; from *S. nanus* and *S. ornatus* by height of the coronoid process ≥ 3.1 mm and ≤ 3.4 mm, respectively; and from *S. tenellus* and *S. vagrans* by il set at an angle $\leq 6^{\circ}$ from the horizontal ramus of the dentary. Additionally, *S. lyelli* can be distinguished from *S. nanus* by length of $ml \geq 1.3$ mm, length of $cl-m3 \geq 4.2$ mm, and length of dentary ≥ 6.5 mm.

Sorex merriami (Merriam's shrew)

Sorex merriami can be distinguished from S. arizonae, S. hoyi, S. longirostris, S. nanus, and S. preblei by height of the coronoid process usually ≥ 3.9 mm; from Notiosorex crawfordi by height of the unpigmented portion of $ml \leq 0.7$ mm; and from S. vagrans by the interdenticular space very shallow (Figs. 13, 22) and il set at an angle $\geq 13^{\circ}$ from the horizontal ramus of the dentary (Fig. 22). It differs from S. hoyi, S. longirostris, S. nanus, and S. preblei by length of $cl-m3 \geq 4.3$ mm and length of the coronoid-condyloid processes ≥ 3.2 mm, and from S. nanus and S. preblei by depth of the dentary below $ml \geq 0.95$ mm. Additionally, Merriam's shrew can be distinguished from S. hoyi by length of $m3 \geq 0.9$ mm, length of the dentary ≥ 6.4 mm, and the alveolus of il not extending posteriorly beneath part of ml (Figs. 3, 22); from S. longirostris by width of $ml \leq 1.0$ mm; and from S. preblei by length of $ml \geq 1.3$ mm and length of the dentary usually ≥ 6.6 mm.

Sorex monticolus (Dusky or Montane shrew)

Sorex monticolus can be distinguished from S. arcticus and S. m. neomexicanus by length of the coronoid-condyloid processes ≤ 3.6 mm and from S. cinereus, S. jacksoni, S. hydrodromus, and S. ugyunak ≥ 3.2 mm; from S. alaskanus, S. bairdii, and S. m. neomexicanus by length of c1-m3 ≤ 5.2 mm and from S. jacksoni, S. hydrodromus, and S. monticolus ≥ 4.5 mm; and from S. arcticus and S. tundrensis by presence of a strip of pigment on the inside of the ventromedial edge of the i1s (Figs. 10, 12).

Additionally, it differs from *S. alaskanus* by length of the dentary ≤ 8.1 mm; from *S. arcticus*, *S. bairdii*, and *S. m. neomexicanus* by height of the coronoid process ≤ 4.2 mm and from *S. ugyunak* ≥ 3.5 mm; from *S. cinereus*, *S. haydeni*, *S. hydrodromus*, *S. jacksoni*, and *S. ugyunak* by length of $ml \geq 1.4$ mm; from *S. jacksoni* by il set at an angle usually $\geq 8^{\circ}$ from the horizontal ramus of the dentary, width of $p4 \geq 0.6$ mm, and width of $m2 \geq 0.7$ mm; and from *S. ugyunak* by il set at an angle usually $\geq 8^{\circ}$ from the horizontal ramus of the dentary, pigment on il usually in one section, and cl usually with one cusp.

Sorex monticolus neomexicanus (Dusky or Montane shrew)

This taxon can be distinguished from *Sorex cinereus*, other *S. monticolus*, and *S. palustris* by height of the coronoid process usually ≥ 4.5 mm. Additionally, this taxon differs from *S. cinereus* and other *S. monticolus* by length of $cI-m3 \geq 5.0$ mm and usually ≥ 5.3 mm, respectively, and length of the coronoid-condyloid processes ≥ 3.7 mm; from *S. cinereus* and *S. palustris* by height of the unpigmented portion of $m1 \geq 0.65$ mm; from *S. cinereus* by length of $m1 \geq 1.6$ mm, length of $m2 \geq 1.3$ mm, and length of the dentary ≥ 7.6 mm; and from *S. palustris* by widths of c1 + p4 usually > 1.4 mm.

Sorex nanus (Dwarf shrew)

With exception of *Sorex minutissimus*, the dwarf shrew is the smallest shrew in North America (Tables 1, 2). Sorex nanus can be distinguished from Notiosorex crawfordi, S. hoyi, S. lyelli, S. merriami, and S. arizonae by height of the coronoid process usually ≤ 3.1 mm. Also, it differs from S. hoyi by the alveolus of il not extending posteriorly beneath part of ml (Figs. 3, 19); from S. preblei by il set at an angle usually $\geq 8^{\circ}$ from the horizontal ramus of the dentary; from S. longirostris by width of $m1 \le 0.8$ mm and width of $m2 \le 0.8$ mm; and from S. tenellus by length of the dentary ≤ 6.5 mm and length of c1–m3 usually ≤ 4.1 mm. Additionally, it can be distinguished from N. crawfordi by length of $c1-m3 \le 4.2$ mm and pigment present on m2 and m3; from S. merriami and S. arizonae by length of the coronoid-condyloid processes ≤ 3.0 mm, depth of the dentary below $ml \le 0.95$ mm, and length of $cl-m3 \le 4.1$ mm; from S. arizonae by length of $c1 \le 0.8$ mm, length of $p4 \le 0.9$ mm, length of $m2 \le 1.1$ mm, width of p4 ≤ 0.6 mm, and length of the dentary ≤ 6.7 mm; and from S. lyelli by length of $ml \le 1.3$ mm, length of $cl-m3 \le 4.1$ mm, and length of the dentary usually ≤ 6.5 mm.

Sorex ornatus (Ornate shrew)

Sorex ornatus can be distinguished from Notiosorex crawfordi by i1 set at an angle usually $\leq 13^{\circ}$ from the horizontal ramus of the dentary, height

of the unpigmented portion of $ml \le 0.7$ mm, and pigment present on m2 and m3; from S. lyelli by height of the coronoid process usually ≥ 3.4 mm and length of the coronoid-condyloid processes ≥ 3.0 mm; and from S. trowbridgii by length of c1–m3 usually ≤ 4.8 mm. No quantitative or qualitative characters of the dentary could be discerned to distinguish S. ornatus from S. vagrans.

Sorex pacificus (Pacific shrew)

This species can be distinguished from *Sorex bendivii* by one posterolingually directed ridge (Figs. 8, 18) on the occlusal surface of p4 and length of $c1 \le$ length of p4.

Sorex palustris (Water shrew)

This species differs from *Sorex bendirii* by one posterolingually directed ridge (Figs. 8, 15) on the occlusal surface of p4 and length of c1 < length of p4; from S. cinereus and S. ugyunak by height of the coronoid process ≥ 4.0 mm and from S. m. neomexicanus usually ≤ 4.5 mm. Additionally, the water shrew differs from S. cinereus and S. ugyunak by length of $m3 \geq 0.95$ mm, length of $c1-m3 \geq 5.2$ mm, i1 set at an angle usually $\geq 8^\circ$ from the horizontal ramus of the dentary, length of the coronoid-condyloid processes ≥ 3.2 mm, and length of the dentary ≥ 8.0 mm; from S. m. neomexicanus by height of the unpigmented portion of $m1 \leq 0.65$ mm and widths of $c1 + p4 \leq 1.4$ mm; and from S. ugyunak by pigment on i1 in one section, length of $p4 \geq 1.1$ mm, width of $m2 \geq 0.8$ mm, and c1 usually with one cusp.

Sorex preblei (Preble's shrew)

Sorex preblei can be distinguished from Notiosorex crawfordi and S. merriami by height of the coronoid process ≤ 3.3 mm, length of the coronoid-condyloid processes ≤ 2.9 mm, and length of c1- $m3 \leq 4.2$ mm, and from S. hoyi and S. nanus by il set at an angle $\leq 8^{\circ}$ from the horizontal ramus of the dentary. Additionally, Preble's shrew can be distinguished from N. crawfordi by height of the unpigmented portion of $m1 \leq 0.65$ mm and pigment present on m2 and m3; from S. hoyi by the alveolus of il not extending posteriorly beneath part of m1 (Figs. 3, 19); from S. merriami by depth of dentary below $m1 \leq 0.9$ mm, length of $m1 \leq 1.3$ mm, and length of dentary usually ≤ 6.6 mm; and from S. haydeni by height of the coronoid process usually ≤ 3.2 mm and length of c1-m3 usually ≤ 4.1 mm.

Sorex sonomae (Fog shrew)

This species can be distinguished from *Sorex bendirii* by one posterolingually directed ridge (Fig. 8) on the occlusal surface of p4 and length of c1 < length of p4.

Sorex tenellus (Inyo shrew)

The Inyo shrew can be distinguished from *Sorex lyelli* by *i1* set at an angle $\geq 8^{\circ}$ from the horizontal ramus of the dentary (Fig. 20), and from *S. nanus* by length of $c1-m3 \geq 4.2$ mm and length of the dentary usually ≥ 6.4 mm.

Sorex trowbridgii (Trowbridge's shrew)

This species can be distinguished from *Sorex ornatus* by length of cl-m3 usually ≥ 5.0 mm.

Sorex tundrensis (Tundra shrew)

Sorex tundrensis differs from S. hydrodromus, S. jacksoni, and S. ugyunak by height of the coronoid process ≥ 3.7 mm, length of the coronoid-condyloid processes ≥ 3.1 mm, and length of c1- $m3 \geq 4.5$ mm; from S. cinereus, S. jacksoni, S. monticolus, and S. ugyunak by lack of a strip of pigment on the inside of the ventromedial edge of the i1s (Figs. 10, 11). Additionally, it differs from S. cinereus by length of the coronoid-condyloid processes usually ≥ 3.3 mm and from S. ugyunak by pigment on i1 in one or two sections, c1 with one cusp, and depth of the dentary below m1 + height of the coronoid process ≥ 4.7 mm.

Sorex ugyunak (Barren ground shrew)

The barren ground shrew can be distinguished from all other *Sorex* by a combination of height of the coronoid process ≤ 3.2 mm and cI with two cusps. Additionally, it differs from *Sorex alaskanus*, *S. arcticus*, and *S. palustris* by length of $cI-m3 \leq 4.5$ mm, length of the coronoid-condyloid processes ≤ 2.9 mm, and length of the dentary ≤ 6.9 mm; from *S. alaskanus* and *S. arcticus* by depth of the dentary below $mI \leq 1.0$ mm; from *S. alaskanus*, *S. hydrodromus*, *S. palustris*, and *S. tundrensis* by pigment on iI in three sections; and from *S. hydrodromus*, *S. monticolus*, and *S. palustris* by iI set at an angle $\leq 5^{\circ}$ from the horizontal ramus of the dentary. Additionally, *S. ugymak* can be distinguished from *S. arcticus* and *S. tundrensis* by presence of a strip of pigment on the inside ventromedial edge of the iIs (Figs. 10, 20); from *S. arcticus* and *S. palustris* by length of $pI \leq 0.9$ mm; from *S. monticolus* and *S. tundrensis* by length of the coronoid-condyloid processes ≤ 2.9 mm; and from *S. tundrensis* by length of $cI-m3 \leq 4.5$ mm.

Sorex vagrans (Vagrant shrew)

Sorex vagrans can be distinguished from S. cinereus and S. lyelli by length of the coronoid-condyloid processes ≥ 3.1 mm; from S. lyelli by il set at an angle $\geq 8^{\circ}$ from the horizontal ramus of the dentary (Fig. 24); and

from *S. merriami* by the interdenticular space very deep (Figs. 13, 24) and il set at an angle $\leq 13^{\circ}$ from the horizontal ramus of the dentary (Fig. 24). No quantitative or qualitative dentary characters could be discerned to distinguish *S. vagrans* from *S. ornatus*.

UNIVERSITY OF KANSAS NATURAL HISTORY MUSEUM PUBLICATIONS

The University of Kansas Publications, Natural History Museum, beginning with volume 1 in 1946, was discontinued with volume 20 in 1971. Shorter research papers formerly published in the above series are now published as The University of Kansas Natural History Museum Occasional Papers. The University of Kansas Natural History Museum Miscellaneous Publications began with number 1 in 1946. Longer research papers are published in that series. Monographs of the Natural History Museum were initiated in 1970. Authors should contact the editor regarding style and submission procedures before manuscript submission. All manuscripts are subjected to critical review by intra- and extramural specialists; final acceptance is at the discretion of the Director.

This publication is printed on acid-free paper. Occasional Papers and Miscellaneous Publications are typeset using Aldus PageMaker® on a Macintosh computer. ® Natural History Museum, The University of Kansas, Lawrence.

Institutional libraries interested in exchanging publications may obtain the Occasional Papers and Miscellaneous Publications by addressing the Exchange Librarian, The University of Kansas Library, Lawrence, Kansas 66045–2800, USA. Individuals may purchase separate numbers from the Office of Publications, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045–2454, USA.
